Abstract

This paper is based on a framework [3] for a formalization of measures of comparison of fuzzy objects. The purpose is to describe the behaviour of measures of comparison within a given family in order to facilitate the choice of a particular measure. It can be done owing to the discrimination power of a measure. © 2000 Elsevier Science B.V. All rights reserved.

Keywords: Measures of comparison; Discrimination power

1. Introduction

The comparison of two objects is a usual task for many and various domains as psychology, statistics, fuzzy sets theory, ... Indeed, comparisons are useful in classification for the matching step, in clustering for the construction of classes [6,7], in decision making for the search of the best candidate, ...

Comparisons are usually realized by means of a measure of comparison. The used measure is often a distance. But, more and more, a similarity or a dissimilarity measure is chosen. But the choice of an appropriate measure among all available measures in literature is not an easy task. It is linked to the problem of the characterization of relevant properties for the considered task. We have proposed a framework in order to deal with measures of comparison [3]. This framework displays the main families of measures of comparison according to the properties they satisfy.

Hence, the existing measures of comparison can be classified. And it is known that a classification simplify a problem.

However, the problem of the choice of a measure of comparison *within* a same family is still present. This paper proposes a solution to this problem.

This proposed solution lies in the discrimination power of a measure. This way, measures can be compared among themselves according to their behaviour. The analysis of behaviours of measures of comparison is easy owing to a geometrical interpretation. This geometrical interpretation is obvious if variables stepping in family of measures are normalized.

2. Measures of comparison

In [3], we have proposed to formalize a measure of comparison between two fuzzy sets as a function of the common elements and the distinctive elements.

Formally, for any set Ω of elements, let $F(\Omega)$ denote the set of fuzzy subsets of Ω

Definition 1. A fuzzy set measure M is supposed to be given, that is to say a mapping defined on $F(\Omega)$ and taking values in $\mathbb{R}^+$ such that, for all A and for all B in $F(\Omega)$:

$$\text{MI1: } M(A) = 0 \Leftrightarrow A = \emptyset.$$

$$\text{MI2: If } B \subseteq A, \text{ then } M(B) \leq M(A).$$

A fuzzy set measure is close to the definition of an existential evaluator given by [9].

Definition 2. An M -measure of comparison on Ω is a mapping $S: F(\Omega) \times F(\Omega) \rightarrow [0, 1]$ such that $S(A, B) = F_s(M(A \cap B), M(B - A), M(A - B))$, for a given mapping $F_s: \mathbb{R}^+ \times \mathbb{R}^+ \times \mathbb{R}^+ \rightarrow [0, 1]$ and a fuzzy set measure M on $F(\Omega)$.

We denote:

- $X = M(A \cap B)$,
- $Y = M(B - A)$,
- $Z = M(A - B)$.

We are interested in measures of comparison which evaluate the likeliness of two descriptions. We have called them *measures of similitude*.

Definition 3. An M -measure of similitude S on Ω is an M -measure of comparison S such that $F_s(X, Y, Z)$ is nondecreasing with respect to X , nonincreasing with respect to Y and Z .

Remark. Tversky's contrast model [14] is compatible with M -measures of similitude. Indeed, Tversky has given a relation which can be generalized to fuzzy sets [12,13] as follows:

$$S(A, B) = f(A \cap B) / (f(A \cap B) + \alpha f(A - B) + \beta f(B - A))$$

with $\alpha, \beta \geq 0$. This quantity is an f -measure of similitude if f is a fuzzy set measure.

M -measures of similitude can be distinguished more subtly in three types: measures of satisfiability, measures of resemblance and measures of inclusion. In this paper, we focus on the two first types of measures of similitude.

2.1. Measures of satisfiability

A measure of *satisfiability* corresponds to a situation in which we consider a reference object or a class

and we need to decide if a new object is compatible with it or satisfies it. More particularly, measures of satisfiability are appropriate for rule base systems. For example, in [2] or in [1] objects are classified by means of a decision tree. In a decision tree, a node represents a test on the chosen attribute during the learning stage; each edge of this node is associated with a value of the attribute. The classification of a new object comes to find consecutive edges from the root to the leaves. In [2,1], the comparison between the value of an attribute of the new example with test-values associated with each edge is realized by means of a measure of satisfiability.

The satisfiability of a reference description A of $F(\Omega)$ by a new description B defined as a fuzzy subset of Ω has been defined as follows:

Definition 4. An M -measure of satisfiability on Ω is a measure $S(A, B) = F_s(X, Y, Z)$ such that:

- F_s is increasing with respect to X , decreasing with respect to Y and independent of Z .

Let us denote $F_s(X, Y) = F_s(X, Y, Z)$. Then,

- $F_s(X, 0) = 1$ for all X ,
- $F_s(0, Y) = 0$ for all $Y \neq 0$.

With this definition, satisfiability can a priori be different with two pairs of fuzzy sets distinctive only because of the scale. It is desirable that a satisfiability measure depends only on the relative weights of X and Y and not on the scale of the system. In order to obtain an objective measure, we propose to normalize the satisfiability measure.

We consider:

$$x = \frac{X}{\sqrt{X^2 + Y^2}} \quad \text{the reduced intersection,}$$

$$y = \frac{Y}{\sqrt{X^2 + Y^2}} \quad \text{the reduced distinctive feature.}$$

Fig. 1 shows the differences of behaviour between the two definitions of measures of satisfiability.

As $x^2 + y^2 = 1$, the domain of definition of the measure of satisfiability is a quarter of circle. It can be described by a unique argument ϕ , with $\phi = \arctan y/x$. We denote the measure of satisfiability $S(A, B) = \eta(\phi)$.

The conditions of Definition 4 become:

- η is decreasing with respect to ϕ ,

Fig. 1. The effect of the normalization on measures of satisfiability.

- $\eta(\pi/2) = 0$,
- $\eta(0) = 1$.

This new form of a measure of satisfiability, expressed by a unique variable, has the advantage not to be dependent upon the size of the system.

Furthermore, this normalization makes the definition of a measure of satisfiability more simple insofar as the argument is a segment $[0, \pi/2]$ and not a quarter of plan.

There are of course many possible choices for the satisfiability measure η satisfying these three conditions. Among them, let us distinguish the two following forms:

- $\eta_1(\phi) = 1 - (2/\pi)\phi$. It is the linear satisfiability function.
- $\eta_2(\phi) = \cos \phi$. This function has the advantage of presenting a meaningful physical insight. If we represent the reference set A by the $(1, 0)$ vector V_A in Fig. 2. If we describe each set B and its related point (x, y) by a vector V_B from the origin, $\eta_2(\phi)$ is the scalar product $V_A \cdot V_B$. When the two vectors are orthogonal, then the satisfiability vanishes: $S(A, B) = 0$. This is a good signification of orthogonality. More generally, the satisfiability appears

Fig. 2. New representation of a measure of satisfiability.

Fig. 3. Satisfiability measures.

as a projection, and the lack of satisfiability is represented as a deviation in Fig. 2: this is an intuitive notion of satisfiability.

We can also focus on the following measures which are known in the literature:

- $S(A, B) = M(A \cap B)/M(B)$, which is usually defined with M the sigma-count, can also be written: $\eta_3(\phi) = 1/(1 + \tan \phi)$.
- $S(A, B) = 1 - M(B - A)$ was introduced in [4] with $M(A) = \sup_x f_A(x)$ and with the difference

$$f_{A-B}(x) = \begin{cases} f_A(x) & \text{if } f_B(x) = 0, \\ 0 & \text{if } f_B(x) > 0. \end{cases}$$

It can also be written: $\eta_4(\phi) = 1 - \sin \phi$.

Fig. 3 displays the behaviour of various mentioned measures of satisfiability. We can see that:

- η_1 is linearly discriminant: satisfiability decreases linearly with the deviation.

Fig. 4. Construction of a measure of satisfiability with a constant by intervals discrimination power.

- η_2 is discriminant for low satisfiability: a small difference between a set and the reference is tolerated.
- η_4 is discriminant for high satisfiability: a small difference between a set and the reference is not tolerated.

Remark. η_4 and η_2 are symmetrical relatively to $(\pi/4, \frac{1}{2})$: $\eta_4(\pi/2 - \phi) = 1 - \eta_2(\phi)$. η_2 has a low discrimination power for high satisfiability, and a high discrimination power for poor satisfiability, whereas η_4 does exactly the reverse.

- η_3 is discriminant for high and low satisfiability at the same time. For high satisfiability, this measure is between the linearly discriminant measure and the low satisfiability discriminant measure. For low satisfiability, it is between the linearly discriminant measure and the high satisfiability discriminant measure. But it is low discriminant for $\eta(\phi) = \frac{1}{2}$.

We can consider that the *discrimination power* of a measure of satisfiability is given by the derivative $\eta'(\phi)$ of η . For instance, for small and large differences between a set and the reference that is to say for $\phi = 0$ or $\phi = \pi/2$:

- $\eta'_1(\phi) = -2/\pi$, for all ϕ ,
- $\eta'_2(0) = 0$ and $\eta'_2(\pi/2) = -1$,
- $\eta'_3(0) = -1$ and $\eta'_3(\pi/2) = -1$,
- $\eta'_4(0) = -1$ and $\eta'_4(\pi/2) = 0$.

In general, for every possible η , we have

$$\int_0^{\pi/2} \eta'(\phi) d\phi = \eta\left(\frac{\pi}{2}\right) - \eta(0) = -1.$$

This means that the total discrimination power $\eta'(\phi)$ has to be distributed on the $[0, \pi/2]$ interval, but a high discrimination power somewhere implies

a low discrimination power elsewhere, the integral being constant.

Accordingly, it is necessary to choose a measure with a discrimination power suitable for the considered application. This suggests a method of construction of a measure of satisfiability. The choice of the discrimination power is the first step. Then η is obtained by integration of this function $\eta'(\phi)$.

For instance, a function with a high discrimination power for $\eta(\phi) = \frac{1}{2}$ but a low discrimination for $\eta(\phi) = 0$ and $\eta(\phi) = \pi/2$ is needed. This kind of measures means that if a description is not far from the reference, then the satisfiability is near from 1 because the difference is not significative. If a description is very far from the reference, we can consider that the satisfiability is null. The example of this method of self-construction is illustrated in Fig. 4.

Once the behaviour of the wanted measure is known, the measure η can be computed thanks to the discrimination power η' . For instance, the discrimination power can be considered:

- constant by intervals. In this case, η is piecewise linear (see Fig. 4). This rigid shape of function is not very satisfactory for a measure of satisfiability.
- A better measure is derived from a discrimination power with a more gradual form. Let us give two possible solutions:

1. the Lorentz's function:

$$\eta'(\phi) = \frac{1}{1 + (\phi - \phi_0)^2 / \Gamma^2}$$

2. the Gaussian function:

$$\eta'(\phi) = \exp -[(\phi - \phi_0)^2] / \Gamma^2$$

normalized on $[0, \pi/2]$ (see Fig. 5). Γ is a parameter which allows a fine control.

Fig. 5. Discrimination power defined by Lorentz and Gaussian functions.

Finally, we would like to give the example of an interesting function for the measure of satisfiability using the Fermi–Dirac function. The analytic form is

$$F_{FD}(\phi) = \frac{1}{1 + \exp^{(\phi - \pi/4)/\Gamma}}$$

and

$$\eta(\phi) = \frac{F_{FD}(\phi) - F_{FD}(\pi/2)}{F_{FD}(0) - F_{FD}(\pi/2)}$$

$\eta(\phi)$ reflects essentially the Fermi–Dirac function. The above expression is used to ensure that $\eta(0) = 1$ and $\eta(\pi/2) = 0$.

The interest of this function lies on its physical meaning: in a physical system of temperature T , containing a statistical set of states, the Fermi–Dirac function describes the statistical probability that a state of energy ϕ is filled or not, with $\Gamma = kT$, where k is the Boltzmann constant. Hence, it describes the probability of a state to belong to the Fermi sea [5] which is a good illustration of satisfiability. Γ controls the decrease of the curve. The choice of Γ enables to define a measure of satisfiability more or less severe, as shown in Fig. 6.

2.2. Measures of resemblance

We are now interested in resemblance measures.

A measure of *resemblance* is used for a comparison between the descriptions of two objects, of the same level of generality, to decide if they have many common characteristics.

Fig. 6. Fermi-Dirac measure of satisfiability.

Measures of resemblance are appropriate for a case-based reasoning or an instance-based learning. In clustering methods, distances can be replaced by a measure of resemblance. More generally, similarity-based classification methods [10, 11] have to use resemblance measures as soon as all objects have the same level of generality.

Definition 5. An M -measure of resemblance on Ω is a measure $S(A, B) = F_S(X, Y, Z)$ such that:

- F_S is increasing with X and decreasing with Y and Z ,
- $F_S(X, 0, 0) = 1$ for all X ,
- $F_S(X, Y, Z) = F_S(X, Z, Y)$.

M -measures of resemblance which satisfy an additional property of t -transitivity, for a triangular norm t , are extensions of indistinguishability relations [13, 15] to fuzzy sets. In the case where t is the minimum, we obtain extensions of measures of similarity.

M -measures of resemblance satisfying the property of exclusiveness:

$$F_S(0, Y, Z) = 0 \quad \text{for all } (Y, Z) \neq (0, 0)$$

are called *exclusive M-measures of resemblance*. We focus on them in the sequel.

Following our normalization procedure, we define:

$$x = \frac{X}{\sqrt{X^2 + Y^2 + Z^2}},$$

$$y = \frac{Y}{\sqrt{X^2 + Y^2 + Z^2}},$$

Fig. 7. New representation of an exclusive measure of resemblance.

$$z = \frac{Z}{\sqrt{X^2 + Y^2 + Z^2}}$$

for $(X, Y, Z) \neq (0, 0, 0)$. Similarly to the case of measures of satisfiability, this ensures that an exclusive measure of resemblance is not dependent on the scale of the problem.

The domain of study is now restricted to a piece of the unity sphere since $x^2 + y^2 + z^2 = 1$. We now have to find the exclusive resemblance μ which satisfies the symmetry property $\mu(x, y, z) = \mu(x, z, y)$.

Geometrically, the sphere is simply obtained by a rotation of the satisfiability circle around the x -axis (see Fig. 7). The vector representation is still valid.

Let us consider $\rho = \xi(y, z)$ with $\xi(y, z) = \xi(z, y)$. This means that ρ can be described by any symmetrical function with respect to y and z .

Let us look for an expression of $v(x, \rho) = \mu(x, y, z)$. By definition, an exclusive measure of resemblance is symmetrical with respect to (Y, Z) , (see Definition 5). And we have

$$v(0, \rho) = 0 \quad \text{if } \rho \neq 0,$$

$$v(x, 0) = 1 \quad \forall x.$$

Fig. 8. Correspondence between satisfiability measures and exclusive resemblance measures.

These conditions show that the problem has been reduced to a satisfiability measure. We can therefore use again the solution described in the preceding section dealing with satisfiability. With this definition of ρ , an exclusive resemblance appears as a satisfiability where a global distinctive feature ρ is defined by $\rho = \xi(y, z)$, from the two individual distinctive features y and z (see Fig. 8).

We can also consider different exclusive measures of resemblance as we have already done with measures of satisfiability. Let us define $\psi = \arctan(\rho^0/x)$ with $\rho^0 = y + z$.

- $v_1 = 1/(1 + \rho^0/x) = 1/(1 + \tan \psi)$. This measure corresponds to the measure of satisfiability η_3 .

Fig. 9. The effects of different definitions of ρ on exclusive measures of resemblance.

Furthermore, v_1 can also be written as: $S(A, B) = M(A \cap B) / M(A \cup B)$ with M such that: $M(A \cup B) = M(A \cap B) + M(A - B) + M(B - A)$. This measure was introduced in [8].

Other definitions of ρ can be envisaged, for instance:

$$\rho' = \sqrt{y^2 + z^2},$$

or

$$\rho'' = (\sqrt{y} + \sqrt{z})^2.$$

The choice of a particular form of ρ has an effect on the measure of resemblance because this parameter represents distinctive elements. We can note that

$$\rho'' \geq \rho^0 \geq \rho' \quad \forall y, z. \quad (1)$$

As ρ has a decreasing effect on an exclusive measure of resemblance, relation (1) implies that

for a given x and for all y and z ,

$$v''(x, \rho'') \leq v(x, \rho^0) \leq v'(x, \rho'). \quad (2)$$

Relation (2) means that $v''(x, \rho'')$ penalizes more the differences between two sets than $v(x, \rho^0)$ and that

$v(x, \rho^0)$ penalizes more the differences than $v'(x, \rho')$. Furthermore, a particular ρ is sensitive to the symmetry between y and z as illustrated in Fig. 9. Indeed, if differences are unbalanced, it means that $y \gg z$ or $z \gg y$, or inversely, if differences are balanced, it means that $y \approx z$, the behaviours of a given ρ are not the same.

3. Conclusion

This paper gives an explicit method to choose a measure of comparison. This method consists of two major points:

1. The choice of the appropriate family of measures of comparison.
2. The choice of the appropriate measure in the chosen family of measures of comparison.

The first choice was described in detail in [3]. This paper focuses more on the second point. It establishes the notion of *discrimination power* which enables to describe precisely the behaviour of a measure. Therefore, it is possible to choose a particular measure among measures of same family than the chosen one because of its particular power of discrimination.
